

# Dreadnought, HMS

By [John Abbatiello](#)

**Adopted in 1906, HMS *Dreadnought* represented an innovative battleship design that changed the nature of the Anglo-German naval race preceding the Great War. A hybrid Dreadnought battlecruiser design soon followed; by 1914, all major navies measured their strength by the number of Dreadnought battleships and battlecruisers they possessed.**

## Pre-war Battleship Design

Technological development during the steamship age pushed 19<sup>th</sup> century warship design to its limits, featuring battleships mounting large caliber, turreted guns, driven by high output piston steam engines, and protected by steel armor. By the turn of last century, a typical battleship mounted four 12-inch guns in two twin-turrets and was armed with an assortment of intermediate gun batteries throughout the ship. Reciprocating steam engines produced enough power to drive the ships to high speeds, typically fifteen to eighteen knots.

Major drawbacks of these designs included difficulty in fire control for the different caliber ammunition. Also, the steam engines required lengthy periods in port for maintenance overhauls and could not be run at full speed for very long without risking breakdowns.

Early in the 20<sup>th</sup> century, British Admiralty leaders learned of plans by American, Italian and Japanese navies to design and build "all big gun" battleships, a concept publicized by Italian naval engineer [Vittorio Cuniberti \(1854-1913\)](#) in 1903. Led by First Sea Lord, Sir [John Fisher \(1841-1920\)](#), British decision makers designed the HMS *Dreadnought* to steal the lead on the plans of other navies and launch a battleship that would outfight any ship afloat.

## Dreadnought Design Innovations

Fisher's team produced a design that incorporated a number of innovations into a single hull. Chief among HMS *Dreadnought's* design characteristics was a main battery of ten 12-inch guns, mounted in five twin-turrets. The turrets were arranged with one at the bow, one on each wing of the ship's bridge, and two along the centerline to the rear of the superstructure. Thus, the arrangement allowed the ship to fire eight heavy guns in a broadside, as compared to contemporary battleships that could answer only with four heavy guns. HMS *Dreadnought* possessed no intermediate battery, making fire control and ammunition storage less difficult.

Other features included turbine steam propulsion - the first use of lighter, dependable and efficient turbine engines in a battleship.

Dreadnought, HMS - 1914-1918-Online

battleship. These new engines allowed HMS *Dreadnought* to steam at almost twenty-one knots continuously, providing a speed advantage over potential enemy ships that would allow fleets to better close with a retreating enemy, avoid a more numerous enemy, or evade a torpedo threat when present. *Dreadnought* also featured redistributed armor to protect guns, engines, and magazines more effectively. Finally, an innovative bulkhead structure in the interior of the ship made flood control easier, providing better survivability.

A hybrid heavy cruiser design, called a battlecruiser, featured similar characteristics, but possessed less heavy armor and fewer large guns to provide for even higher speed. Fisher's concept for the battlecruiser was for it to be able to chase down any ship it wanted to attack, as well as be able to run from anything more powerful. When necessary, the battlecruiser could join the battle fleet and serve alongside *Dreadnought* battleships, since its large guns could provide a similar offensive capability.

## Ship History

Taking advantage of guns and turrets already completed for other ships and using other prefabricated construction, HMS *Dreadnought* was laid down in February 1906 and commissioned in December of the same year, a remarkable construction record for the time. By comparison, the US Navy's first Dreadnought-style battleships, the USS *South Carolina* and USS *Michigan*, were laid down in December 1906 and not completed until early 1910. Thus, in a single stroke Fisher and the Royal Navy stole the lead on other navies planning to produce an "all big gun" battleship and made all other battleships obsolete.

As newer and larger *Dreadnought* designs joined the Royal Navy, the original vessel served as flagship for the Home Fleet from 1907 to 1911. During the First World War, HMS *Dreadnought* gained fame by being the only battleship to sink a [submarine](#) when she rammed U-29 in March 1915. During the [Battle of Jutland](#), she was in refit and thus never actually fired a shot in anger during the war. After the war, she was sold for scrap along with most of her consorts and broken up in early 1923.

## Impact

Contemporaries and historians have criticized Fisher for wiping the slate clean and negating [Britain's](#) advantage in pre-Dreadnought battleships. A new [naval race](#) with [Germany](#) began in 1906 but Britain would never lose its lead in battleships; by the outbreak of the war, Britain possessed twenty-nine Dreadnought battleships and battlecruisers while Germany only had seventeen. At the Battle of Jutland on 31 May 1916, 249 ships engaged in a massive naval battle that included fifty-eight Dreadnought battleships and battlecruisers, thirty-seven of them British and twenty-one of them German.

Indeed, HMS *Dreadnought* provided her name to a new concept for battleship design that would continue to improve through the Second World War. The world's final battleship class afloat, the US Navy's *Iowa* class that served until the 1990s, owed its existence to the Admiralty's leaders from the early years of the century.
